

An Example Problem

Principal Component Analysis

- Given an $n \times d$ matrix A , compute a good rank k subspace Q

$$A \approx A \cdot Q \cdot Q^T$$

A

\approx

A

Q

Q^T

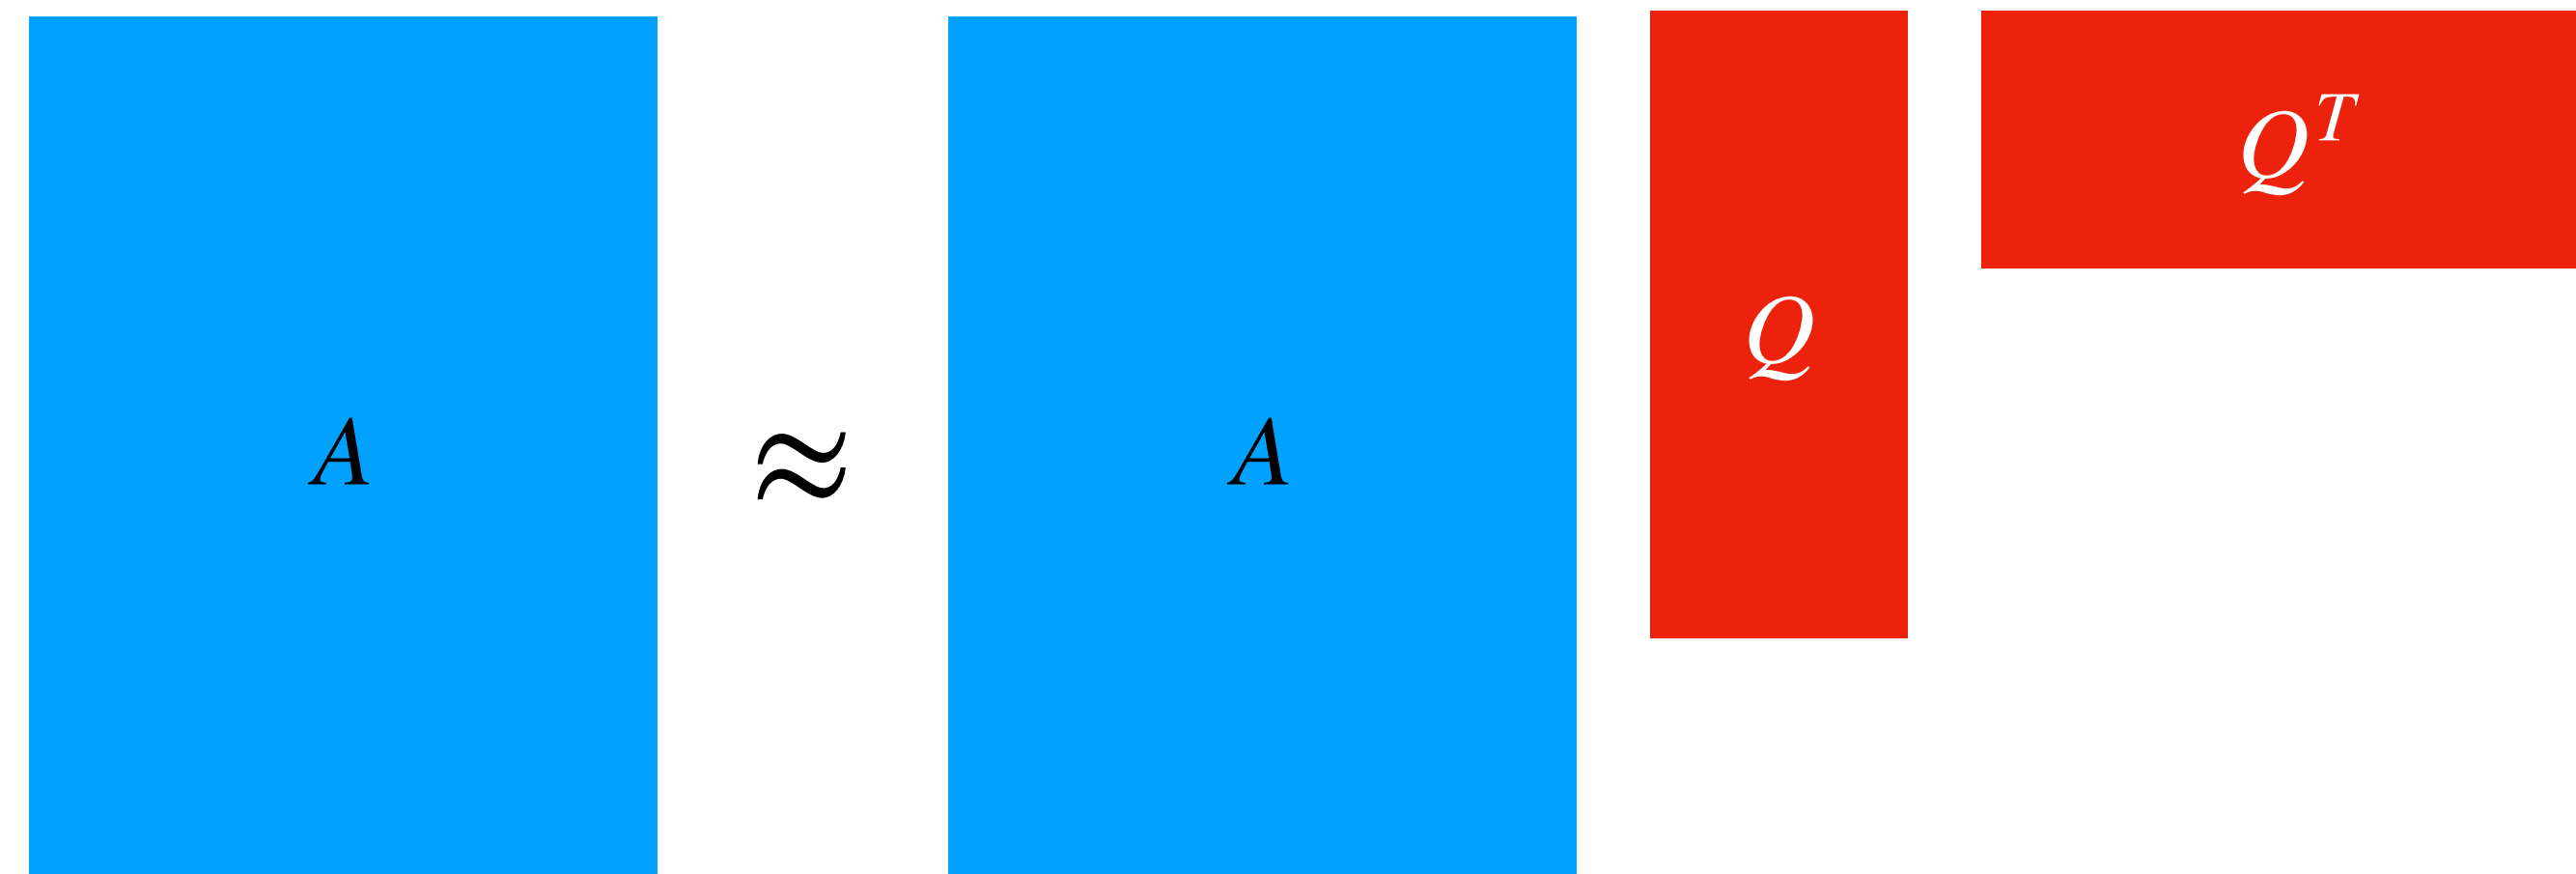

- Columns of Q are the Principal Components

An Example Problem

Principal Component Analysis

- Given an $n \times d$ matrix A , compute a **good** rank k subspace Q

$$A \approx A \cdot Q \cdot Q^T$$

- Columns of Q are the **Principal Components**

Classic Setting

- The matrix A is available to us and can be arbitrarily accessed
- Compute SVD : nd^2 time
 - Very slow on modern datasets
 - Does not utilize sparsity
