An Example Problem

Principal Component Analysis

- Given an $n \times d$ matrix A, compute a **good** rank k subspace Q

$$A \approx A \cdot Q \cdot Q^T$$

$$A \approx A \, Q \, Q^T$$

- Columns of Q are the **Principal Components**

An Example Problem
Principal Component Analysis

- Given an $n \times d$ matrix A, compute a **good** rank k subspace Q

$$A \approx A \cdot Q \cdot Q^T$$

- Columns of Q are the **Principal Components**

Classic Setting

- The matrix A is available to us and can be arbitrarily accessed

- Compute SVD : nd^2 time

    - Very slow on modern datasets

    - Does not utilize sparsity
